Exercise 1

We use the lexicographic ordering to assign a numerical index to each of the 24 = 4! permutations. Let,

	$f: \mathbb{Z}_{24} o S_4$	f(x) =	
$0 \mapsto [0,1,2,3]$	$6 \mapsto [1, 0, 2, 3]$	$12 \mapsto [2,0,1,3]$	$18 \mapsto [3,0,1,2]$
$1 \mapsto [0,1,3,2]$	$7 \mapsto [1,0,3,2]$	$13 \mapsto [2,0,3,1]$	$19 \mapsto [3,0,2,1]$
$2 \; \mapsto \; [0,2,1,3]$	$8 \mapsto [1, 2, 0, 3]$	$14 \mapsto [2, 1, 0, 3]$	$20 \mapsto [3, 1, 0, 2]$
$3 \mapsto [0, 2, 3, 1]$	$9 \mapsto [1, 2, 3, 0]$	$15 \mapsto [2, 1, 3, 0]$	$21 \mapsto [3, 1, 2, 0]$
$4 \mapsto [0,3,1,2]$	$10 \mapsto [1, 3, 0, 2]$	$16 \mapsto [2, 3, 0, 1]$	$22 \mapsto [3, 2, 0, 1]$
$5 \mapsto [0,3,2,1]$	$11 \mapsto [1, 3, 2, 0]$	$17 \mapsto [2, 3, 1, 0]$	$23 \mapsto [3, 2, 1, 0]$

Part (a)

For the transition matrix, take for instance the base permutation, [0, 1, 2, 3], which has index 0. The 3 possibilities according to the shuffling rules in this case are:

$$f(0) = [0, 1, 2, 3] \rightarrow [1, 0, 2, 3] = f(6),$$

$$f(0) = [0, 1, 2, 3] \rightarrow [1, 2, 0, 3] = f(8),$$

$$f(0) = [0, 1, 2, 3] \rightarrow [1, 2, 3, 0] = f(9).$$

Therefore for the 0-th row in the transition matrix,

$$\Pi_{0,6} = \Pi_{0,8} = \Pi_{0,9} = 1/3,$$

and the rest of the entries are 0. The complete transition matrix would be:

Now, to evaluate the uniformity of n shuffles we are going to calculate, for multiple n's, the uniform error e_n ,

$$e_n = ||U - \Pi^n||_{\infty} = \max_{i,j} (|\Pi_{i,j} - 1/24|),$$

where U is a matrix where all entries are 1/24. This matrix represents the transition matrix for perfectly uniform shuffles.

Part (b)

Now, for this new set of shuffling rules, we have the following transition matrix:

Then, with the same formula as the previous part, we have the following errors.

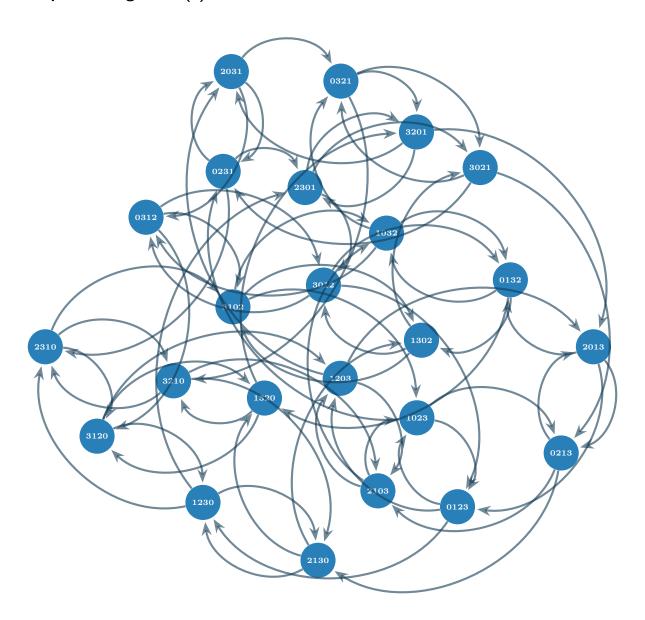

$$e_1 = 20.83333\%$$
 $e_2 = 14.58333\%$ $e_3 = 9.89583\%$
 $e_4 = 5.59896\%$ $e_5 = 5.20833\%$ $e_6 = 4.50033\%$
 $e_7 = 4.2745\%$ $e_8 = 4.2394\%$ $e_9 = 4.19057\%$
 $e_{10} = 4.1797\%$ $e_{11} = 4.1756\%$ $e_{12} = 4.16979\%$

The error seems to oscillate between $\pm 4.1667\%$. In fact, the error matrix seems to have the following behavior:

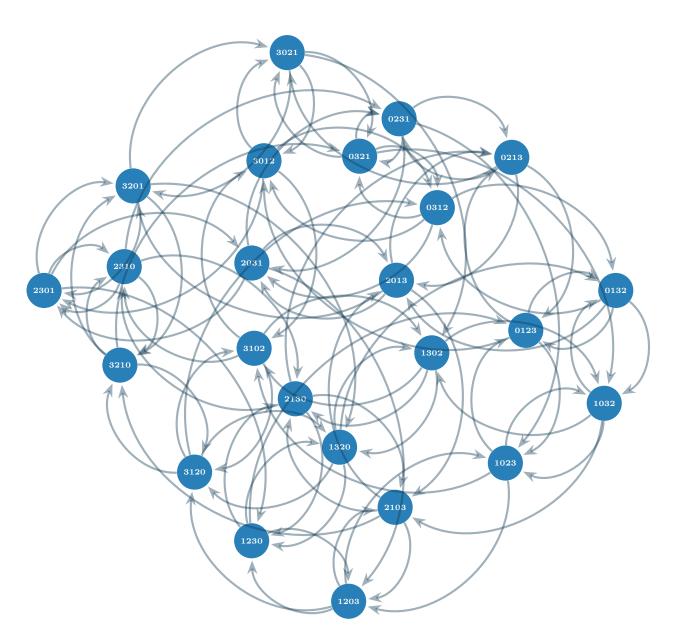

$$\Pi^n - U \approx -(\Pi^{n+1} - U),$$

and $|(\Pi - U)_{i,j}| \approx 4.1667\%$, and thus, the error never seems to converge to 0.

Graph Drawings Part (a)

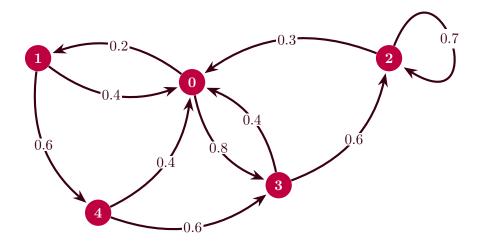

Graph Drawings Part (b)

Exercise 2

$$\Pi = \frac{1}{10} \cdot \begin{bmatrix} 0 & 2 & 0 & 8 & 0 \\ 4 & 0 & 0 & 0 & 6 \\ 3 & 0 & 7 & 0 & 0 \\ 4 & 0 & 6 & 0 & 0 \\ 4 & 0 & 0 & 6 & 0 \end{bmatrix}$$

Part (a)

Part (b)

Let $\Theta \sim \text{UNI}[0,1]$, the function f for the dynamical system that is defined by the previous transition matrix is:

$$\begin{split} f(0,\Theta) &= 1 \cdot \mathbbm{1}_{[0,2)}(10\Theta) + 3 \cdot \mathbbm{1}_{[2,10]}(10\Theta), \\ f(1,\Theta) &= 0 \cdot \mathbbm{1}_{[0,4)}(10\Theta) + 4 \cdot \mathbbm{1}_{[4,10]}(10\Theta), \\ f(2,\Theta) &= 0 \cdot \mathbbm{1}_{[0,3)}(10\Theta) + 2 \cdot \mathbbm{1}_{[3,10]}(10\Theta), \\ f(3,\Theta) &= 0 \cdot \mathbbm{1}_{[0,4)}(10\Theta) + 2 \cdot \mathbbm{1}_{[4,10]}(10\Theta), \\ f(4,\Theta) &= 0 \cdot \mathbbm{1}_{[0,4)}(10\Theta) + 3 \cdot \mathbbm{1}_{[4,10]}(10\Theta). \end{split}$$

Part (c)

Now, with the formula

$$\mathbf{E} [T_4 \mid X_0 = i] = x_i = 1 + \sum_{j \neq i} \Pi_{i,j} x_j,$$

we get the following linear system for the expected value of the time of the first return to 4,

$$\begin{array}{rcl} 10x_0 & = & 10 + 2x_1 + 8x_3 \\ 10x_1 & = & 10 + 4x_0 + 6x_4 \\ 10x_2 & = & 10 + 3x_0 + 7x_2 \\ 10x_3 & = & 10 + 4x_0 + 6x_2 \\ 10x_4 & = & 0. \end{array}$$

The equivalent system to solve is

$$\begin{bmatrix} 10 & -2 & 0 & -8 & 0 \\ -4 & 10 & 0 & 0 & -6 \\ -3 & 0 & 10 & 0 & 0 \\ -4 & 0 & -6 & 10 & 0 \\ 0 & 0 & 0 & 0 & 10 \end{bmatrix} \begin{bmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} 10 \\ 10 \\ 10 \\ 10 \\ 0 \end{bmatrix}.$$

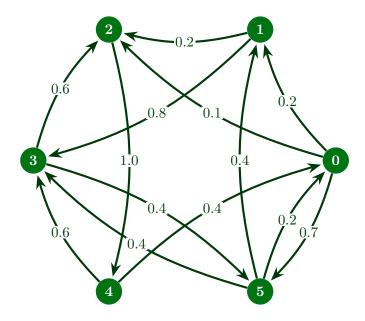

Then,

$$\begin{bmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} 5.44 \\ 3.18 \\ 2.63 \\ 4.75 \\ 0 \end{bmatrix}$$

Exercise 3

$$\Pi = \frac{1}{10} \cdot \begin{bmatrix} 0 & 2 & 1 & 0 & 0 & 7 \\ 0 & 0 & 2 & 8 & 0 & 0 \\ 0 & 0 & 0 & 0 & 10 & 0 \\ 0 & 0 & 6 & 0 & 0 & 4 \\ 4 & 0 & 0 & 6 & 0 & 0 \\ 2 & 4 & 0 & 4 & 0 & 0 \end{bmatrix}$$

Part (a)

Part (b)

Let $\Theta \sim \text{UNI}[0,1]$, the function f for the dynamical system that is defined by the previous transition matrix is:

$$\begin{split} f(0,\Theta) &= 1 \cdot \mathbbm{1}_{[0,2)}(10\Theta) + 2 \cdot \mathbbm{1}_{[2,3]}(10\Theta) + 5 \cdot \mathbbm{1}_{[3,10]}(10\Theta), \\ f(1,\Theta) &= 2 \cdot \mathbbm{1}_{[0,2)}(10\Theta) + 3 \cdot \mathbbm{1}_{[2,10]}(10\Theta), \\ f(2,\Theta) &= 4, \\ f(3,\Theta) &= 2 \cdot \mathbbm{1}_{[0,6)}(10\Theta) + 5 \cdot \mathbbm{1}_{[6,10]}(10\Theta), \\ f(4,\Theta) &= 0 \cdot \mathbbm{1}_{[0,4)}(10\Theta) + 3 \cdot \mathbbm{1}_{[4,10]}(10\Theta), \\ f(0,\Theta) &= 0 \cdot \mathbbm{1}_{[0,2)}(10\Theta) + 1 \cdot \mathbbm{1}_{[2,6]}(10\Theta) + 3 \cdot \mathbbm{1}_{[6,10]}(10\Theta), \end{split}$$

Part (c)

Similar to the previous part, we get the following linear system for the expected time of return to state 4:

$$\begin{array}{rcl} 10x_0 & = & 10 + 2x_1 + 1x_2 + 7x_5 \\ 10x_1 & = & 10 + 2x_2 + 8x_3 \\ 10x_2 & = & 10 + 10x_4 \\ 10x_3 & = & 10 + 6x_2 + 4x_5 \\ 10x_4 & = & 0 \\ 10x_5 & = & 10 + 2x_0 + 4x_1 + 4x_3 \end{array}$$

Then,

$$\begin{bmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} = \begin{bmatrix} 5.63 \\ 4.17 \\ 1 \\ 3.71 \\ 0 \\ 5.27 \end{bmatrix}$$
